1. Dataset Structure

This dataset contains patient-level information related to oral cancer cases.

The `str()` function shows that the dataset contains 84,922 observations and 25 variables. It includes a mix of numeric and character variables representing demographics, risk factors, clinical symptoms, and treatment outcomes.

Output width was limited to prevent result from exceeding page margins in this document.

```r
str(oral_data, width = 90, strict.width = "cut")
```

```
## 'data.frame':    84922 obs. of  25 variables:
##  $ ID                                     : int  1 2 3 4 5 6 7 8 9 10 ...

##  $ Oral.Cancer..Diagnosis.                : chr  "No" "Yes" "Yes" "No" ...
```

2. Variables in Dataset

The `names()` function lists all 25 variables in the dataset. These include demographic information (e.g., Age, Gender, Country), risk factors (e.g., Tobacco Use, Alcohol Consumption, HPV Infection), clinical indicators, and outcome variables such as survival rate and treatment cost.

```r
names(oral_data)
```

```
##  [1] "ID"
##  [2] "Country"
##  [3] "Age"
##  [4] "Gender"
##  [5] "Tobacco.Use"
##  [6] "Alcohol.Consumption"
##  [7] "HPV.Infection"
##  [8] "Betel.Quid.Use"
##  [9] "Chronic.Sun.Exposure"
## [10] "Poor.Oral.Hygiene"
## [11] "Diet..Fruits...Vegetables.Intake."
## [12] "Family.History.of.Cancer"
## [13] "Compromised.Immune.System"
## [14] "Oral.Lesions"
## [15] "Unexplained.Bleeding"
## [16] "Difficulty.Swallowing"
## [17] "White.or.Red.Patches.in.Mouth"
## [18] "Tumor.Size..cm."
## [19] "Cancer.Stage"
## [20] "Treatment.Type"
## [21] "Survival.Rate..5.Year...."
## [22] "Cost.of.Treatment..USD."
## [23] "Economic.Burden..Lost.Workdays.per.Year."
## [24] "Early.Diagnosis"
## [25] "Oral.Cancer..Diagnosis."
```

3. Preview of Data

The `head()` function displays the first 15 rows of the dataset, providing a quick overview of how the data is organized.

```r
head(oral_data, 15)
```

```
##    ID      Country Age Gender Tobacco.Use Alcohol.Consumption HPV.Infection
## 1   1        Italy  36 Female         Yes                 Yes           Yes
## 2   2        Japan  64   Male         Yes                 Yes           Yes
## 3   3           UK  37 Female          No                 Yes            No
## 4   4    Sri Lanka  55   Male         Yes                 Yes            No
## 5   5 South Africa  68   Male          No                  No            No

```

4. User-Defined Function

A user-defined function is created to calculate a simple risk score based on selected risk factors, including tobacco use, alcohol consumption, HPV infection, family history, and immune system status. Each factor contributes a weighted value to produce an overall score for demonstration purposes.

```r
risk_score <- function(tobacco, alcohol, hpv, family_history, immune_system) {
  (tobacco == "Yes") * 2 +
  (alcohol == "Yes") +
  (hpv == "Yes") * 2 +
  (family_history == "Yes") +
  (immune_system == "Yes")
}

risk_score(oral_data$Tobacco.Use[1],
           oral_data$Alcohol.Consumption[1],
           oral_data$HPV.Infection[1],
           oral_data$Family.History.of.Cancer[1],
           oral_data$Compromised.Immune.System[1])
```

```
## [1] 5
```

5. Filter Rows Based on Criteria

An example filter is applied based on the following conditions:

- Stage 1 cancer
- Tumor sizes less than 5 cm
- From Sri Lanka
- Over the age of 60
- Female
- No tobacco use
- No betel quid use

The narrow criteria result in a small subset of patients, in this case older females from Sri Lanka with early-stage cancer and generally fewer high-risk behaviors.

```r
oral_data %>% filter(
  oral_data$Cancer.Stage == 1,
  oral_data$Tumor.Size..cm. < 5,
  oral_data$Country == "Sri Lanka",
  oral_data$Age > 60,
  oral_data$Gender == "Female",
  oral_data$Tobacco.Use == "No",
  oral_data$Betel.Quid.Use == "No")
```

```
##       ID   Country Age Gender Tobacco.Use Alcohol.Consumption HPV.Infection

6. Identifying Dependent & Independent Variables

The dataset contains multiple potential independent and dependent variables; a subset has been selected for demonstration purposes.

Independent variable: **Tumor Size**
Dependent variable: **Cost of Treatment**

```
head(data.frame(oral_data$Tumor.Size..cm., oral_data$Cost.of.Treatment..USD.), 15)
```

```
##    oral_data.Tumor.Size..cm. oral_data.Cost.of.Treatment..USD.

```

7. Data Cleaning and Adjustments

Basic data cleaning steps are demonstrated, including **removing missing values**, **eliminating duplicate** records, **sorting** the data in descending order by treatment cost, and **renaming** selected columns for clarity. In this dataset, no missing values or duplicate records were observed. Columns such as alcohol consumption and treatment cost were renamed for readability as part of the demonstration.

```
clean_data = oral_data %>% filter(!is.na(Cost.of.Treatment..USD.))
clean_data = clean_data %>% distinct()

clean_data = clean_data %>% arrange(desc(Cost.of.Treatment..USD.))

clean_data = clean_data %>% rename(
  Drinker = Alcohol.Consumption,
  Treatment.Cost.USD = Cost.of.Treatment..USD.
)
head(clean_data, 5)
```

```

```

8. Adding New Variables to the Data Frame

A new variable, **cost per cm**, is created by dividing **treatment cost** by **tumor size**. This demonstrates how derived variables can be added to the dataset for further analysis.

```r
clean_data = clean_data %>% mutate(cost.per.cm = Treatment.Cost.USD / Tumor.Size..cm.)
head(clean_data, 5)
```

```

9. Creating a Training Set

A training set is created by randomly sampling 5% of the dataset using a fixed seed (1234) to ensure reproducibility. This demonstrates how subsets of data can be generated for modeling or testing purposes.

```r
set.seed(1234)
training_data = clean_data %>% sample_frac(0.05, replace = FALSE)
head(training_data, 5)
```

```

10. Summary of the Main Data Set

The `summary()` function provides an overview of the dataset.

From the output, many values for tumor size and treatment cost are zero, which may indicate placeholder or missing entries. The median tumor size and cancer stage are also zero, suggesting many cases are recorded at early or minimal levels. Additionally, a large number of missing values appear in cost per cm, due to division by zero when tumor size is zero.

```r
summary(clean_data)
```

```

11. Statistical Functions on the Dataset

Mean, **median**, and **range** of treatment costs.

Basic statistical measures such as mean, median, and range are calculated for treatment cost. The mean cost is approximately 39,110 USD, while the median is 0, indicating that a large portion of the dataset contains zero-cost entries. The range spans from 0 to 159,988 USD, showing a wide variation in treatment costs.

```r
mean(clean_data$Treatment.Cost.USD, na.rm = TRUE)
```

```
## [1] 39109.88
```

```r
median(clean_data$Treatment.Cost.USD, na.rm = TRUE)
```

```
## [1] 0
```

```r
range(clean_data$Treatment.Cost.USD, na.rm = TRUE)
```

```
## [1]      0 159988
```

R does not have a built-in `mode()` function for statistical mode (most frequent value). The `mode()` function in R refers to the data type of an object. So the following code was executed to determine the statistical **mode** of cancer stage in the dataset; this code can be put in a user-defined function for reusability, but the following is included to illustrate the steps taken.

The most common cancer stage in the dataset is 0, which aligns with earlier observations that many cases are recorded at early or minimal stages.

1. `table()` is used to count how many times each cancer stage appears.

```
cancer_stage_count = table(clean_data$Cancer.Stage)
cancer_stage_count
```

```
##
##     0     1     2     3     4
## 42573 12713 12865 10520  6251
```

2. Sort the counts from highest to lowest.

```
cancer_stage_count = sort(cancer_stage_count, decreasing = TRUE)
cancer_stage_count
```

```
##
##     0     2     1     3     4
## 42573 12865 12713 10520  6251
```

3. **Obtain the cancer stage with the highest count.**

```
names(cancer_stage_count)[1]
```

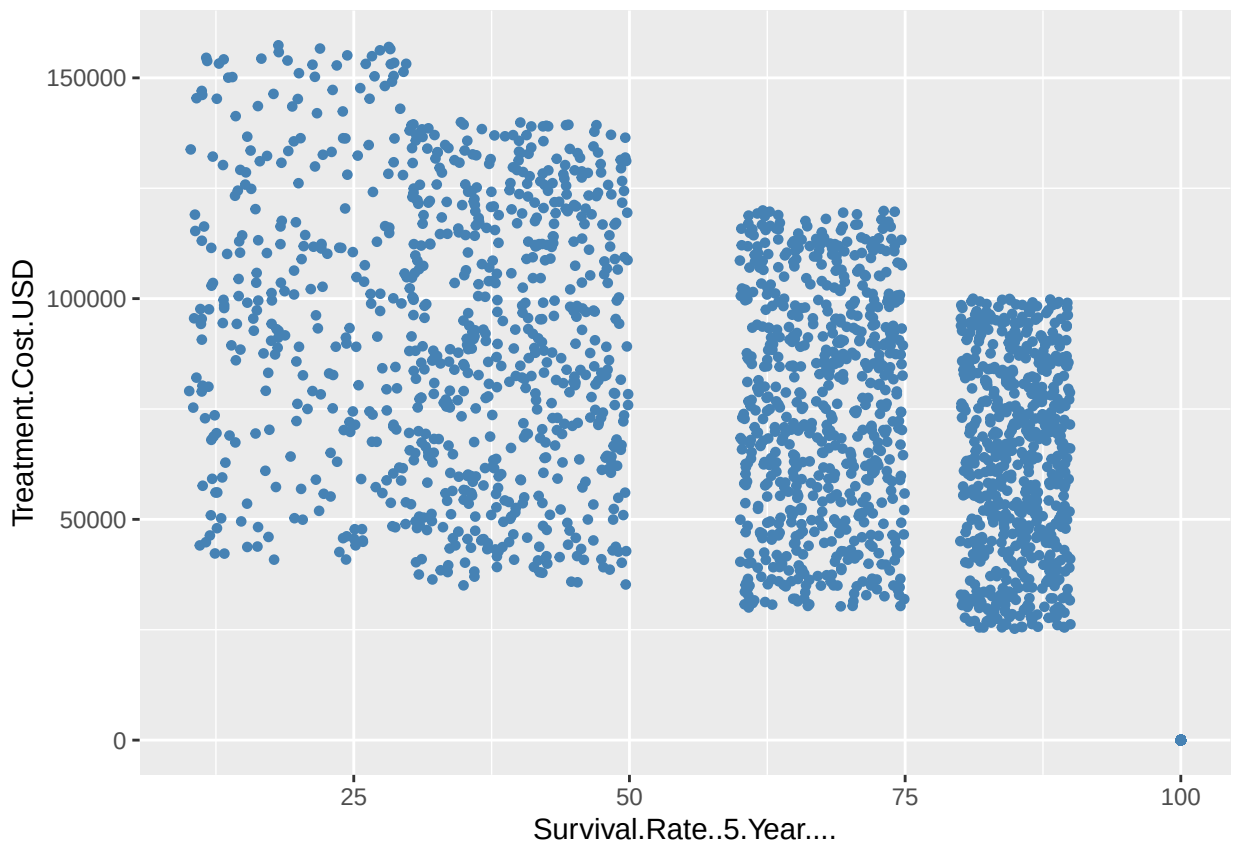
```
## [1] "0"
```

12. Scatter Plot

A scatter plot is created to visualize the relationship between **survival rate (5 years)** and **treatment cost**.

The plot shows a slight negative relationship between survival rate and treatment cost. The distribution is not fully continuous, as points form clusters at certain values, which may reflect how the data is structured around specific treatment or disease categories. Despite these clusters, there is still variability within groups, suggesting that treatment cost is not solely determined by survival rate.

```
ggplot(data = training_data, aes(x = Survival.Rate..5.Year...., y = Treatment.Cost.USD)) +
  geom_point(color = "steelblue", size = 1.2)
```

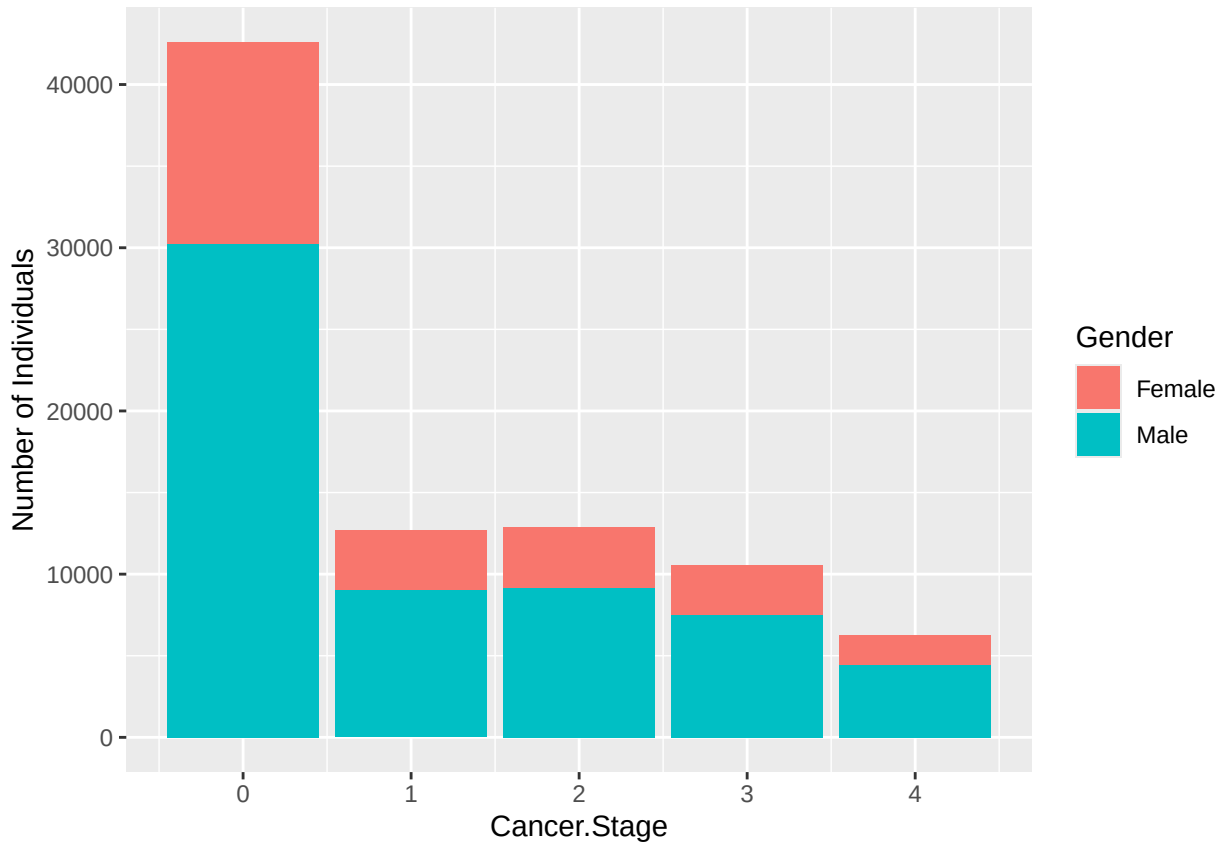


13. Bar Plot

A bar plot is created to display the **number of individuals at each cancer stage**, grouped by **gender**.

From the plot, stage 0 has the highest number of individuals, with counts decreasing as cancer stage increases. Males appear to have higher counts than females across all stages, although the overall distribution trend is similar for both groups.

```
ggplot(data = clean_data, aes(x = Cancer.Stage, fill = Gender)) + geom_bar() +
  ylab("Number of Individuals")
```



14. Pearson Correlation

A correlation value close to 1 or -1 indicates a strong linear relationship. The Pearson correlation between **treatment cost** and **survival rate** is approximately -0.8, indicating a strong negative correlation, where higher survival rates are generally associated with lower treatment costs. While the scatter plot of the same variables (Section 12) shows high variability, the overall downward trend still results in a strong negative correlation.

```
cor(clean_data$Treatment.Cost.USD, clean_data$Survival.Rate..5.Year...., method="pearson")
```

```
## [1] -0.8066187
```
